Background

To date, no treatments for natalizumab related progressive multifocal leukoencephalopathy (PML) exist. In order to limit the infection spreding in the brain, the use of plasma exchange (PLEX) is highly recommended. Although effective in removing NTZ, PLEX might be detrimental for patient outcome. Indeed, PLEX may increase the likelihood of the development of immune reconstitution inflammatory syndrome (IRIS) from the rapid restoration of immunosurveillance, which will eventually worsen the clinical symptoms and the possibility of inflammatory brain damage. Despite this concerns, the effectiveness of PLEX has never been sistematically investigated.

Objective

To retrospectively compare the clinical outcome and survival of Italian and international cases of natalizumab-associated Progressive Multifocal Leukoencephalopathy (NTZ-PML) treated or not with (PLEX).

Table 1. Descriptive characteristics of the population

| | PLEX+ | PLEX- | p |
|--|---|---|--------------|
| | n = 184 | n = 35 | |
| Sex, n (%) | (1 (22) | 4 (11) | 0.02 |

The percentages were estimated from the number of available observations

The number of available observations for PLEX+/PLEX-: a182/35, b54/20, c183/34, d40/16, e168/30, f52/6, g66/20, b72/25. Abbreviations: PLEX, plasmapheresis; PML, progressive multifocal leukoencephalopathy; SD, standard deviation; US, United States; ROW, rest of world; EDSS, Expanded Disability Status Scale; NTZ, natalizumab; CSF-JCV, cerebrospinal fluid-JC virus; IRIS, immune reconstitution inflammatory syndrome

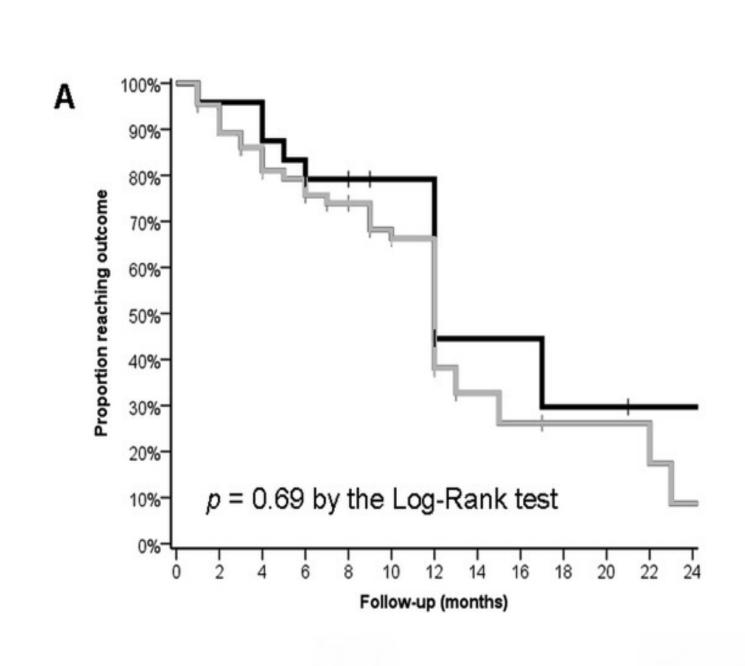

Methods

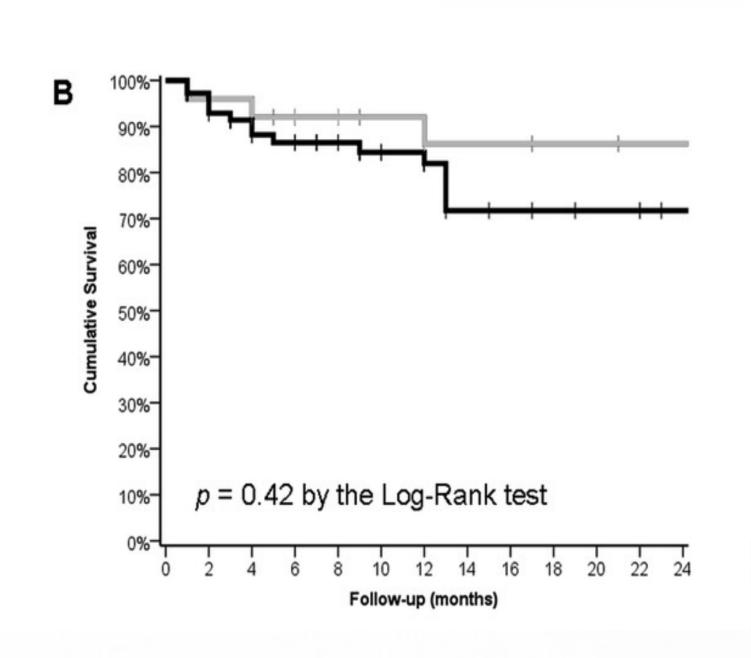

Medical literature was searched for the terms "Natalizumab" and "Progressive Multifocal Leukoencephalopathy". Data on 193 NTZ-PML cases, extracted from 49 papers out of 487, aggregate to data derived from 34 Italian cases, were analyzed. Clinical outcome (improved, stable, worsened, dead) was defined comparing clinical status at PML diagnosis and after PML resolution. Death from any cause after PML diagnosis was considered an event in survival analysis. The effect on clinical outcome and survival of PLEX, age, country, lesions location at diagnosis, CSF-JCV status, PML-IRIS was analyzed both by univariate and multivariate analyses using logistic regression models.

Results

PLEX did not reduce the mortality risk [Hazard Ratio (HR), 1.25; confidence interval (CI), 0.40-3.92; p=0.7] or the likelihood of bad versus favorable outcomes (HR, 1.25; CI, 0.68-2.32; p=0.47). At multivariate analysis country (US and ROW) was predictive of mortality (HR, 5.78; CI, 0.97-34.36; p=0.05) and bad outcome (HR, 3.87; CI, 1.78-8.42; p=0.001), while PML-IRIS development (HR, 4.61; CI, 1.10-19.39; p=0.04) was predictive of bad outcome.

Discussion

These findings suggested that the spontaneous recovery of immunocompetence after NTZ withdrawal might counteract the spread of PML in patients with MS and therefore not require any additional intervention. Nevertheless, forcing the rapid restoration of immune surveillance in the brain with PLEX may eventually expose patients to an increased risk of aggressive PML-IRIS. Considering the potential risks and costs of PLEX, we believe that these results argue for caution and for individualized decision-making regarding PLEX. The clinical relevance of this problem justifies the performance of prospective clinical studies in order to identify the patients who will more likely benefit from PLEX in NTZ-PML treatment.
